API Modification Requirements

Nullable fields, independent marketplace location, updated 5 km discovery logic, and home-screen active orders

DOCUMENT TYPE	DOCUMENT DATE	PRIORITY
Backend API Change Request	30 July 2026	Required Update

Overview

The following changes are required to make selected fields optional, separate marketplace location from the user profile location, apply marketplace discovery using each marketplace's own stored coordinates, and return a limited active-order list on the customer home screen.

1

Make Service Description Optional

POST post-service-request	POST direct-hire
---------------------------	------------------

Required Change

The description field must be nullable because users may submit a service request or direct-hire request without providing a description.

Backend Behaviour

Accept the request when description is omitted, null, or empty according to the project's existing input-normalization rules.

Update validation from required to nullable/optional while keeping the existing string and length checks when a value is provided.

Do not change the remaining request flow or existing required fields.

2

Make Product Sale Price Optional

POST marketplace/product/add

POST/PATCH
marketplace/product/update/{productId}

Required Change

The sale_price field must be nullable because a seller may add or update a product without offering a discounted price.

Backend Behaviour

Allow sale_price to be omitted or submitted as null.

When sale_price is provided, keep the existing numeric and business validation rules.

When sale_price is not provided, the product should remain available using its regular price only.

Marketplace Location Updates

3

Store Marketplace Location Separately

POST/PATCH update-profile

POST become-seller

Required Change

Marketplace location must be stored independently from the user's personal profile location. The current implementation uses the user location as the marketplace location; this must be separated.

Backend Behaviour

Add dedicated marketplace address and coordinate fields following the project's existing naming conventions.

Updating a marketplace location must not overwrite the user's personal profile location.

The become-seller flow must accept and save the marketplace's own location.

The update-profile flow must support updating marketplace location separately for seller accounts.

4

Apply the 5 km Radius Using Marketplace Coordinates

GET user-home**GET marketplace/get-all**

Required Change

Marketplace results are currently returned within a 5 km radius. After introducing a separate marketplace location, distance filtering must use the marketplace's own latitude and longitude instead of the seller/user profile coordinates.

Backend Behaviour

Use the requesting user's current coordinates as the search origin.

Use each marketplace's stored marketplace coordinates as the destination point for distance calculation.

Return only marketplaces located within the existing 5 km radius.

Do not fall back to the user profile location for marketplaces that already have their own location.

5

Return the First Four Active Marketplace Orders

GET user-home

Required Change

The user-home API must return the first four active marketplace orders for the authenticated customer.

Backend Behaviour

Apply this requirement only for an authenticated customer.

Return a maximum of four marketplace orders with active status.

Use the project's existing default ordering so the first four relevant active orders are returned consistently.

Keep the existing user-home response structure and add the data using the project's established response-key conventions.

Expected Result

OPTIONAL INPUTS

Requests and products can be submitted without description or sale price.

INDEPENDENT LOCATION

Marketplace coordinates remain separate from the user profile location.

ACCURATE DISCOVERY

The 5 km filter uses the actual marketplace location for nearby results.

CUSTOMER HOME ORDERS

The authenticated customer receives up to four active marketplace orders on user-home.

All updates should follow the existing API response structure, authentication rules, and project coding conventions.
